### Exercise 1.1

In below expressions, the result printed by the interpreter is given. It's assumed that the sequence is to be evaluated in the order they are presented.

```
10
10
(+534)
12
(-91)
8
(/ 6 2)
(+ (* 2 4) (- 4 6))
(define a 3)
implementation dependent a = 3
(define b (+ a 1))
implementation dependent b = 4
(+ a b (* a b))
19
(= a b)
false
(if (and (> b a) (< b (* a b)))
    b
    a)
(cond ((= a 4) 6)
      ((= b 4) (+ 6 7 a))
      (else 25))
16
(+ 2 (if (> b a) b a))
6
```

### Exercise 1.2

Translation of the following expression into prefix notation

```
\frac{5+4+(2-(3-(6+\frac{4}{5})))}{3(6-2)(2-7)} (/ (+ 5 \\ 4 \\ (- 2 (- 3 \\ (+ 6 \\ (/ 4 5))))) \\ (* 3 \\ (- 6 2) \\ (- 2 7)))
```

#### Exercise 1.3

Definition of a procedure that takes three numbers as arguments and returns the sum of the squares of the two larger numbers.

#### Exercise 1.4

Description of the behavior of the following procedure with the observation that our model of evaluation allows for combinations whose operators are compound expressions.

```
(define (a-plus-abs-b a b)
((if (> b 0) + -) a b))
```

The sub-expression (if (> b 0) + -) will evaluate to + if b > 0 and - otherwise. So, the body of the procedure will become

- (+ a b) if b > 0
- (- a b) if  $b \leq 0$

In sum, the procedure a-plus-abs-b is computing a + |b|.

#### Exercise 1.5

Ben Bitdiddle has invented a test to determine whether the interpreter he is faced with is using applicative-order evaluation or normal-order evaluation. He defines the following two procedures:

```
(define (p) (p))
(define (test x y)
```

```
(if (= x 0)
0
y))
```

Then he evaluates the expression (test 0 (p)).

Let's devise the behavior that Ben will observe with an interpreter that uses

• Applicative-order evaluation

The interpreter will evaluate the arguments at first and (p) will call itself and will be an infinite loop that never ends.

• Normal-order evaluation

The interpreter will first expand the expression (test 0 (p)) into

```
(if (= 0 0)
0
(p))
```

As (= 0 0) evaluates to true, the consequent 0 will be evaluated and the procedure evaluation will terminate with the result 0.

#### Exercise 1.6

Alyssa P. Hacker doesn't see why if needs to be provided as a special form. "Why can't I just define it as an ordinary procedure in terms of cond?" she asks. Alyssa's friend Eva Lu Ator claims this can indeed done, and she defines a new version of if:

Eva demonstrates the program for Alyssa:

```
(new-if (= 2 3) 0 5)
5
(new-if (= 1 1) 0 5)
```

Delighted, Alyssa uses new-if to rewrite the square-root program:

When Alyssa attempts to use new-if to compute square roots, it will end into a never ending evaluation. In fact, according to the substitution model for procedure evaluation, the operands of new-if will be evaluated before applying the operation on them. It will then evaluate sqrt-iter call even if the guess is already good enough. The later would call another iteration, and so on...

## Exercise 1.7

The good-enough? test used in computing square roots will not be very effective for finding square roots of very small numbers because the margin of error could be higher than the number itself.

```
e.g.
(square (sqrt 0.0000001))
; Value: 9.76629102245155e-4
```

For very large numbers, the procedure evaluation can take very long.

e.g.

```
(sqrt 1e100)
```

The evaluation of this expression causes the interpreter to become stuck.

An alternative strategy for implementing <code>good-enough?</code> is to watch how <code>guess</code> changes from one iteration to the next and to stop when the change is very small fraction of the guess.

```
(define (good-enough? guess x)
  (< (abs (- guess (improve guess x))) (* 0.0001 guess)))</pre>
```

Using this new definition of good-enough? the previous expressions are respectively more accurate and terminable within a reasonable time.

```
(square (sqrt 0.0000001))

; Value: 1.0001264334838593e-7

(sqrt 1e100)

; Value: 1.000000633105179e50
```
